

## #2 Problem

Since from problem 1, we can use check for how many times does a character appears in between 2 strings. We could then go a step further to create some array, in my logic, I think array would be the best because then we can loop through the array and say that if a character at `text1[i] == text2[j]`, then we store that specific letter or character into the new array and then return them at the end.
